

Turbidity

Resistor values are from the
datasheet.

pH (+/- 600mV)

ORP (+/- 1.8V)

Calibration Input

Ext Temperature Sense NTC 10k

Assuming a B[25/50] of 4250 (from ERTJ thermistor manual)
@0 R=3.582*10k = 35820
@25 R=1 * 10k = 10k
@100 R=0.5353 * 10k = 5353
With a top resistor of 10k and a bias of 4.096 we have an
output range of [3.451, 4.4281] delta = 2.023V range.
This is about 0.020mV / C for that range. That corresponds
to about 20 LSB / C less nonlinearity.

Ext Temperature Sense PT-1000 Probe (960-11560hm)

Gain = 27
1k precision resistor gives
@0C R=1k
@25C R=1097.3
@40C R=1155.4
With a top resistor of 1k and a bias of 4.096 we have an
output range of [2.048, 2.196] delta = 0.148V range.
This is about mV / C which corresponds to about
LSB / C.

Atlas Scientific Isolated Carrier Board

NOTE!!! The header socket is flipped for mounting the
carrier board upsidedown.

This is initially for the Atlas Scientific Conductivity board.
It is required to initialize the EC-EZO module to I2C comms.
See the EZO-EC datasheet for more information.

Dissolved Oxygen (Analog) 4.2mV = 100% saturation (probe)

Note that the Atlas Scientific DO board is simply a
5-3.3V regulator coupled with a non-inverting amp with
10x gain on it. 100% saturation is 42mV out of the
A.S. board so I'm assuming the probe outputs a max of
4.2mV. We will simply use a 960X gain stage here giving
us very nearly full scale at 100% saturation.

GAIN = 960x

We need a powered output and switch for the LED ring. Ideally, a constant-current LED driver would be used although I'd like to keep the option open to use a multi-spectral led source which will probably want one channel per LED. For now, maybe just a constant-current serial output?

NOTE: The ESP32 carrier board has headers on the bottom. Thus the carrier board header socket pinout is identical to the ESP32 board as viewed from above.
